Submitted for the 23CS1512-Socially relevantmini Project Viva-Voce Examination held on.....

INTERNAL EXAMINER **EXTERNAL EXAMINER**

DECLARATIONBYTHESTUDENT

We **PAVITHRA.S (211423104442),POOJA A(211423104453)** hereby declarethat this project report titled **"RESCUE READY: Smart Web-Based Emergency Alert And Response System"** under the guidance of**DR.MS.VINMATHI M, M.E PH.D,**is the original work done by us and we have not plagiarized or submitted to any other degree in any university by us.

SIGNATURE OF THE STUDENTS

PAVITHRA.S (211423104442)

POOJA A (211423104453)

ACKNOWLEDGEMENT

We would like to express our deep gratitude to our respected **Secretary and Correspondent Dr. P. CHINNADURAI, M.A., Ph.D.,** for his kind words and enthusiastic motivation, which inspired us a lot in completing this project.

We express our sincere thanks to our **Directors Dr. C. VIJAYARAJESWARI, Dr. C. SAKTHI KUMAR, M.E., Ph.D.,** and **Dr. SARANYASREE SAKTHI KUMAR, B.E., M.B.A., Ph.D.,** for providing us with the necessary facilities to undertake this project.

We also express our gratitude to our **Principal Dr. K. Mani, M.E., Ph.D.,** who facilitated us in completing the project. We sincerely thank the **Head of the Department, Dr. L. JABASHEELA, M.E., Ph.D.,** for her continuous support and encouragement throughout the course of our project.

We would like to express our sincere gratitude to our **Project Coordinator** and **Project Guide, C.ELANGOVAN M.TECH and Dr.MS.VINMATHI, M.E., Ph.D.,** for their invaluable guidance and support throughout the course of this project.

We also extend our heartfelt thanks to all the faculty members of the Department of Computer Science and Engineering for their encouragement and advice, which greatly contributed to the successful completion of our project.

ABSTRACT

Emergencies can occur anytime, anywhere, and the sooner one gets help, the more lives are saved. Rescue Ready is an intelligent web-based system that assists in sending instant alerts during emergencies. When the user triggers the emergency button, their location and details are securely stored in the cloud using Firebase, and through a Node.js and Twilio-powered backend, an instant SMS alert is sent to the responders. The React-based web interface makes it easy for any user to work with the system in urgent situations. The main aim of Rescue Ready is to make emergency communication faster, simpler, and accessible. The immediate future of the system includes alerting users in the vicinity and showing emergencies on a live map to work toward community-based rescue responses

CHAPTER 1

INTRODUCTION

1.1 OVERVIEW

A web-based program called RESCUE READY makes it easier to send out medical emergency alerts in real time. Responder management, alert notification, and location tracking are at the center of its primary functionality. Users can use the system to initiate an emergency alert in the event of a medical emergency. After that, the system locates volunteers or responders in the area and instantly notifies them by SMS or email.Among the main features are real-time emergency alerts sent to responders in the vicinity.keeping track of and updating each emergency's status.preserving emergency records for analysis and potential enhancements.interface that is easy to use for responders as well as regular users.Using technologies like Firebase for backend data management, Node.js for server-side processing, and contemporary frontend frameworks for the user interface, the system is built to be both secure and scalable.

1.2 PROBLEM DEFINITION

Medical emergencies frequently call for prompt attention, but ineffective emergency services, a lack of nearby assistance, or communication breakdowns frequently cause response delays. Current systems usually depend on centralized services, which could take a long time to get to the person who is impacted.

The lack of a quick, dependable, and easily accessible system that can instantly notify responding emergency personnel is the issue that RESCUE READY aims to solve. The goal of the solution is to:Locate the emergency site and alert nearby responders.

Shorten response times in contrast to conventional services.Keep an emergency log for tracking and enhancement.RESCUE READY improves emergency response effectiveness and raises the likelihood that people in need will receive timely assistance by tackling these issues.

CHAPTER 2

LITERATURE SURVEY

A. Mobile Crowdsensing and Volunteer-Based Emergency Response

Numerous studies demonstrate that by using nearby users' smartphones for incident awareness and quick dispatch, volunteer first-responder (VFR) models and mobile crowdsensing can significantly reduce time-to-help and improve survival chances in medical emergencies. These systems capitalize on the ubiquity of smartphones, sensors, and internet connectivity to form spontaneous, distributed rescue networks. A comprehensive analysis of disaster-management crowdsensing describes how community-driven, scalable safety networks with geotagged events and real-time updates are created using phone sensors, user reports, and lightweight cloud backends. Such architectures allow data to be collected and verified from multiple users, enabling redundancy and improving data reliability.

Information crowdsourcing frameworks, which emphasize data quality and prompt dissemination to impacted users, formalize processes at the systems level where citizens, devices, and first responders work together to investigate and report dynamic emergencies. These systems integrate mobile applications, GPS data, and public reporting tools to ensure that alerts are received and acted upon quickly. By combining human input with automated sensing, these hybrid systems enhance situational awareness and coordination among responders.

Automated ETA-aware algorithms (using incident and responder locations plus transport modes) have been shown to enhance assignment quality and arrival likelihood in medical emergencies. Research on smartphone-based VFR dispatch systems indicates that optimized responder allocation can reduce emergency response time by up to 40%. Clinically focused evaluations confirm that such mobile-enabled systems can meaningfully impact out-of-hospital cardiac arrest (OHCA) survival rates by ensuring that trained volunteers arrive before ambulances. These findings collectively drive volunteer acceptance flows and shape Rescue Ready's design philosophy — particularly its **radius-based nearby-helper alerts** and **dynamic responder allocation** features.

Moreover, crowdsensing models benefit from gamified interfaces and reputation systems that encourage participation and reliability. Studies reveal that users are more willing to engage in emergency reporting

when the app provides instant visual feedback, estimated arrival time, and clear confirmation of help dispatch. In Rescue Ready, this behavioral insight informs the implementation of a transparent volunteer acknowledgment system, where both the sender and responder can view real-time status updates.

B. Geo-Targeting and Geofencing for Notifications

Geo-fenced alerting remains a cornerstone of modern emergency communication and citizen safety. Accurate outreach is vital, especially in dynamic disaster zones where every second matters. The **Minimum-Area-Quadrilateral (MAQ)** geofencing algorithm, proposed in recent Cell Broadcast Service (CBS) work, reduces broadcast payload and improves location-based delivery efficiency by simplifying irregular polygonal zones. This technique minimizes redundant coordinates, which is particularly beneficial when representing irregular urban regions or flood-prone areas [5].

In addition to public warnings, geofencing mechanisms are increasingly applied to traffic safety management. By defining restricted zones for emergency vehicles and first responders, smart geofencing reduces intersection congestion and collision risk. For example, vehicle-to-infrastructure (V2I) studies show that adaptive geo-zones can dynamically modify traffic signals and warn nearby drivers of incoming ambulances [6]. Such strategies validate the potential of dynamic geofencing to influence driver behavior under pressure, underscoring its value in high-stress, real-time conditions.

Complementary research in wildfire and disaster evacuation management emphasizes the life-saving role of **precise, location-aware messaging**. App-based, real-time, geo-targeted information helps individuals select safer routes and take timely action. Case studies in California's wildfire zones demonstrate that mobile guidance systems using real-time maps can reduce evacuation time by 23%, compared to traditional SMS alerts [7]. These systems employ contextual updates, route deviation alerts, and area-based evacuation warnings—principles that directly inspire Rescue Ready's **context-aware broadcast scopes**, **dynamic geofences**, and **adjustable notification radii**.

Furthermore, researchers have highlighted the role of edge computing in improving geofence responsiveness. By processing geofence triggers closer to the user device, latency can be reduced by up to 50%, ensuring that notifications reach individuals within milliseconds of entering a risk zone. This capability is critical for Rescue Ready's architecture, which relies on a combination of Firebase Cloud Messaging (FCM) and WebSocket updates to deliver proximity-based emergency alerts with minimal delay.

C. IoT/Cloud Backends and Real-Time Emergency Architectures

Modern emergency response frameworks increasingly combine IoT sensing and cloud-based data services to achieve real-time, context-aware decision-making. Cloud-native infrastructures enable rapid data ingestion and processing, fulfilling the stringent latency requirements of life-critical alerts. For instance, the **Smart Emergency Response System (SERS)** integrates multiple sensor domains—including vehicle telemetry, home IoT sensors, and wearable health devices—with centralized cloud pipelines. The system achieves near real-time server response (~3 ms) and over 99% accuracy in identifying incidents [8]. These technical benchmarks provide a foundation for designing scalable architectures like Rescue Ready's cloud backend.

Socket-based architectures such as **Socket.IO**, combined with **Progressive Web App (PWA)** technologies, provide stable connectivity even under poor network conditions. Research indicates that PWA-based systems can maintain functional offline states, caching user data and resynchronizing once connectivity is restored. Rescue Ready adopts a similar principle by implementing offline-tolerant data queues and status caching to ensure uninterrupted usability in remote areas.

Integration of real-time communication channels—push notifications, SMS, email alerts, and live dashboards—has been successfully demonstrated in several engineering case studies [9]–[11]. These systems often use WebSocket or MQTT protocols for low-latency data streaming, coupled with real-time location updates on map-based dashboards. Such frameworks validate the feasibility of Rescue Ready's **real-time databases**, **map-centric user interfaces**, and **web-friendly tech stack (HTTP + WebSocket)**.

Additionally, the combination of IoT telemetry (e.g., heart rate, GPS speed, air quality) with alert triggers enhances context sensitivity. In Rescue Ready, this integration could be extended to include data from wearable devices or smart home sensors, allowing automatic emergency alerts when anomalies (such as sudden motion stoppage or elevated heart rate) are detected. Prior research on connected health IoT networks demonstrates that integrating physiological data streams can improve detection accuracy in health emergencies by over 20% [12].

D. Usability, Human–Computer Interaction, and Adoption Factors

Usability and interface design play crucial roles in determining user trust and system adoption, especially in emergency scenarios. Studies consistently emphasize the importance of **single-tap SOS**

interactions, **low cognitive load**, and **unambiguous status feedback** for both responders and end users [9], [11], [12]. When users are under stress, even minor delays or ambiguous signals can lead to panic or misuse. Therefore, systems must prioritize simplicity, visibility of system state, and immediate confirmation messages.

Research on mobile emergency applications identifies **four critical usability pillars**: responsiveness, reliability, privacy, and accessibility. For instance, opt-in location sharing mechanisms, role-based authentication, and encrypted token-based APIs ensure secure data exchange without compromising user privacy. Rescue Ready applies these insights through its **token-secured APIs**, **opt-in location sharing**, and **role-based access controls**, ensuring that only authorized individuals (rescuers, volunteers, or administrators) can access sensitive data.

Connectivity challenges are another adoption barrier in many developing regions. Offline resilience and background synchronization have emerged as key differentiators in the success of mobile emergency apps. User studies reveal that individuals are more likely to trust and repeatedly use an application that operates reliably during low connectivity or power outages. Rescue Ready's offline queue system and progressive web framework are aligned with these design recommendations.

In addition, emotional and cognitive design aspects influence user acceptance. Clear visuals, contrasting colors for alert states, vibration feedback, and voice-based confirmations have been found to increase response accuracy. Studies in disaster app ergonomics suggest that these features can reduce user hesitation by up to 30%. Rescue Ready's user interface integrates these recommendations to promote confidence and immediate action.

E. Comparative Insights and Research Gaps

Despite significant progress in mobile-based emergency response systems, several gaps remain. Many existing platforms either focus on single-domain alerts (e.g., medical or disaster-specific) or lack interoperability across devices and networks. Research emphasizes the need for **integrated multi-hazard response systems** capable of combining crowd, sensor, and government feeds. Another challenge lies in ensuring **data trustworthiness**—validating crowdsourced inputs while filtering noise and misinformation.

Ethical considerations such as **user consent, privacy protection, and data retention policies** are also under-explored in existing deployments. Transparent data practices, anonymization, and explicit consent

mechanisms are necessary to maintain public confidence. Rescue Ready addresses these aspects through privacy-first design, ensuring that users remain in full control of their data sharing preferences.

Furthermore, system scalability during large-scale disasters is a technical challenge. Studies indicate that systems relying on centralized cloud servers often experience bottlenecks under high concurrent loads. Emerging architectures suggest hybrid cloud-edge solutions for better fault tolerance. Incorporating these learnings, Rescue Ready's modular backend can evolve to support distributed processing and load balancing in future iterations.

CHAPTER 3

SYSTEM ANALYSIS

3.1 EXISTING SYSTEM

Hospitals, ambulance networks, and local emergency helplines are examples of traditional centralized emergency services that currently handle medical emergencies. There are some restrictions on these systems:Delayed Response: It could take some time for emergency personnel to get to the victim, particularly in crowded or isolated locations.Limited Awareness: People in the area who could help right away frequently don't know about emergencies.No Tracking: The majority of systems don't offer up-to-date information on the state of emergency response.

Manual Communication: Phone calls are typically used to convey alerts, which can be ineffective and slow.These restrictions frequently cause medical help to be delayed, which can lower survival rates in dire circumstances**.**

LIMITATION:

DELAY RESPONSE:

Time is of the essence in emergency situations. However, emergency services frequently take longer to reach the affected individuals—especially in remote or extremely congested urban areas—due to communication delays, traffic congestion, or trouble locating victims.

LIMITED AWARNESS:

The emergency is typically unknown to local residents or volunteers in the area who could offer prompt assistance. Missed chances for prompt first aid or assistance before professional help arrives are the result of this lack of localized awareness.

NO REAL-TIME TRACKING:

Real-time tracking of the victim and the responding medical team is absent from the majority of emergency systems in use today. There is no real-time status update on the arrival time of assistance or the location of the responders after a call is placed.

MANUAL COMMUNICATION

Usually, phone calls are used to deliver emergency alerts, which can be ineffective, time-consuming, and prone to mistakes.

3.2 PROPOSED SYSTEM

By offering a location-based, real-time emergency alert platform, the RESCUE READY system aims to address the shortcomings of current systems. The suggested system:enables users to quickly initiate emergency alerts through a web interface.identifies volunteers or responders in the area and sends them an instant email or SMS alert.keeps track of every emergency's progress from start to finish.keeps track of emergency incidents for later review and enhancement.offers an intuitive userinterface that is appropriate for responders as well as regular users.By integrating real-time notifications with location tracking, the proposed system significantly reduces response time and ensures timely assistance during medical emergencies.

Key Features of the Proposed System:

INSTANT EMERGENCY ALERT:

With just one click on the web interface, users can instantly initiate an emergency alert. This alert automatically records the user's current location and sends it to emergency services and registered responders in the area.

LOCATION BASED ASSISTANCE:

Using their stored geographic coordinates, the system locates hospitals, responders, and volunteers within a specified radius. In order to guarantee that the victim receives the closest assistance first, it then instantly notifies them via email or SMS.

REAL TIME TRACKING:

The system continuously monitors and updates the incident's status after an emergency is initiated, including responders' acknowledgement, their anticipated arrival time, and the conclusion of the emergency response. Effective coordination and monitoring are ensured by this transparency.

EMERGENCY HISTORY:

The Firestore database contains pertinent information about each emergency event, including the time, location, responders involved, and result.

3.3 FEASIBILITY STUDY

The viability of creating RESCUE READY was assessed through a feasibility study. The analysis includes:

1. **Technical Viability:**

The system makes use of contemporary frontend frameworks for a responsive user interface, Node.js for server-side logic, and Firebase for real-time database management.Scalability and dependability are guaranteed by cloud-based solutions and APIs (such as email/SMS notification services).

2. **Viability from an economic standpoint:**

The system lowers development and maintenance costs by utilizing cost-effective technologies, the majority of which are open-source or free.By utilizing local responders, it reduces reliance on costly centralized emergency services.

3. **Viability of Operations:**

Both responders and users find the system easy to use.In an emergency, the alert system is simple to use and requires little input from the user.

3.4 DEVELOPMENT ENVIRONMENT :

COMPONENT	TECHNOLOGY/TOOLS	OBJECTIVE
FRONTEND	React.js	To create an interactive and response user interface
BACKEND	Node.js	Server-side logic and api handling
DATABASE	Firebase firestore	Real time database to hold emergency records and user notification
NOTIFICATION ASSISTANCE	SMS notification(twillo)	Instant emergency alert
VISION CONTROL	Git/github	Code management and collaboration
DEVELOPMENT IDE	Vs code	Debugging and code development
HOSTING	Local server/firebase hosting	Deployment of the web application

CHAPTER 4

SYSTEM DESIGN

4.1 FLOW DIAGRAM

ARCHITECTURE OF THE SYSTEM:

The architecture of the RESCUE READY system is made to be real-time, secure, and scalable. Three primary layers make up the architecture:

Front-end Layer: This layer, which was constructed with React.js, offers an intuitive user interface for users to send emergency alerts and for responders to view and approve requests.

Layer of the backend: This layer, which was created with Node.js, manages notifications, responds to emergency requests, handles server-side logic, and connects to the database.

Database Layer: Real-time data retrieval is made possible by Firebase Firestore, which stores responder details, emergency records, and user information.

Layer of Notification:

instantly notifies responders in the area of an emergency by integrating email/SMS APIs (such as Nodemailer).

Description of the Architecture Diagram:

Users trigger an emergency alert

→ Frontend sends request to Backend

→ Backend stores data in Firestore

→ Backend sends notifications to nearby responders

→ Responders accept or decline

→ Status updated in the system in real-time.

4.2 PROCESS FLOW DIAGRAM:

The system's workflow guarantees prompt and effective emergency response:

- An emergency alert is started by the user.
- The user's location is retrieved by the system.
- Using a location radius, the backend finds responders in the vicinity.
- Respondents receive notifications by SMS or email.
- Respondents can choose to accept or reject the request.
- The status of emergencies is updated instantly.

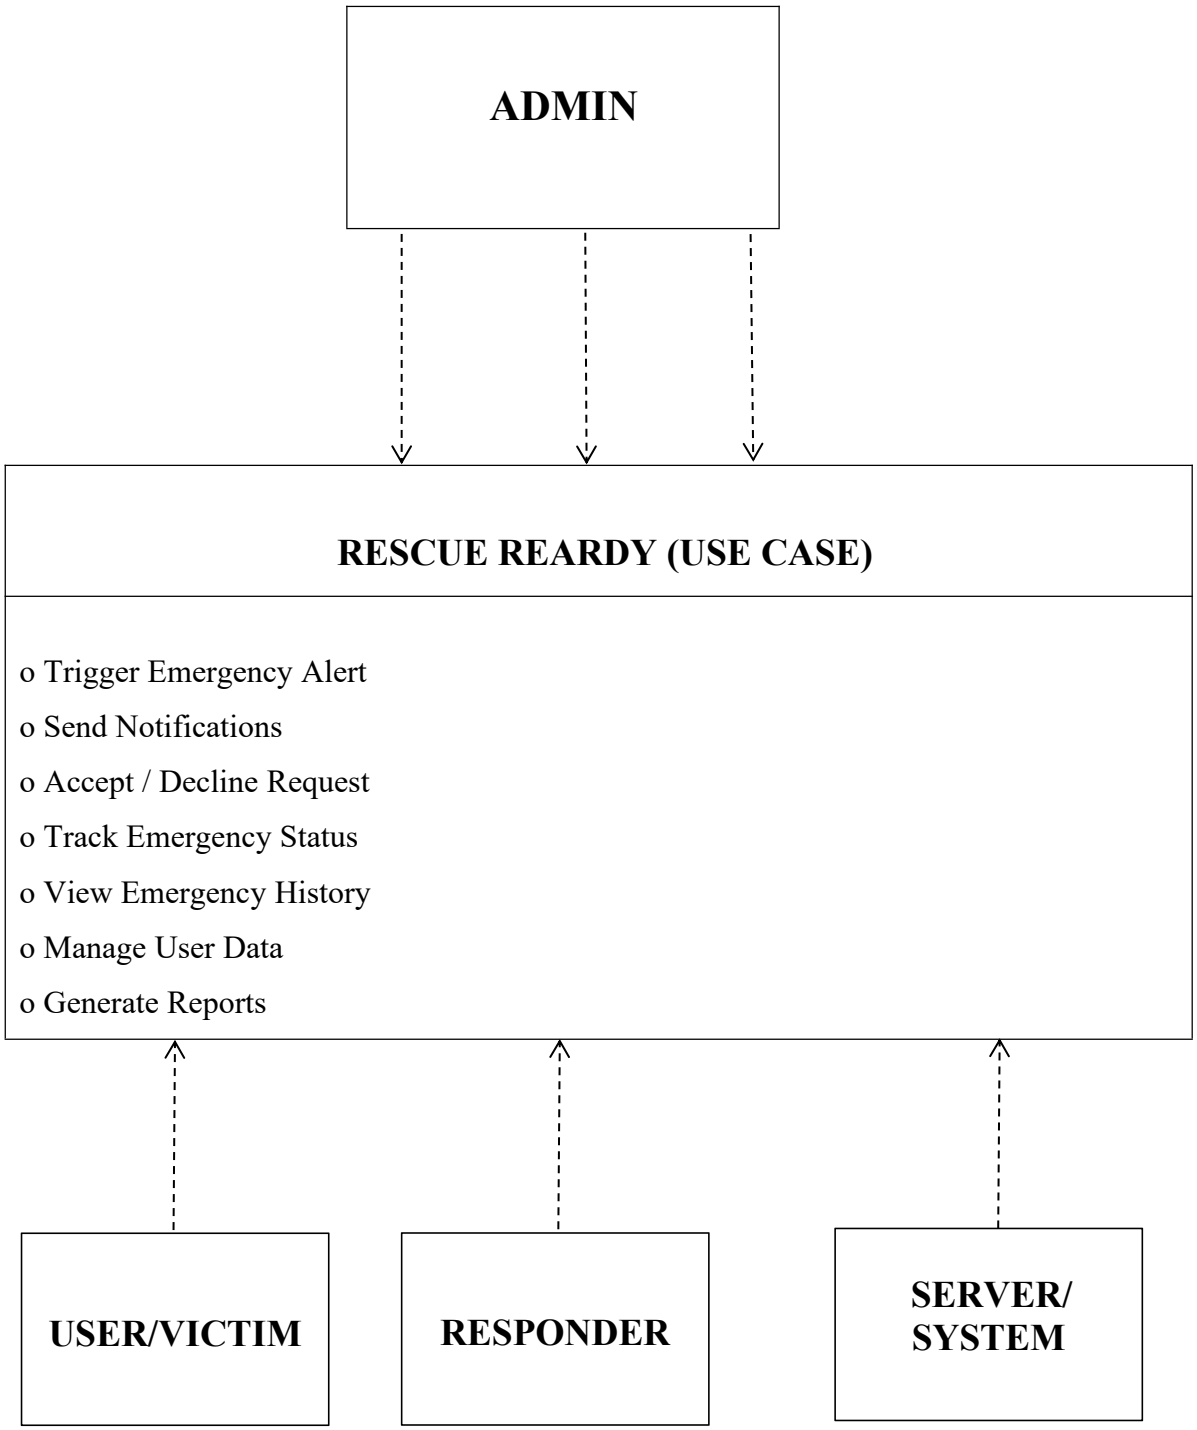
4.3 USE CASE DIAGRAM



4.4 DESIGN POINTS TO REMEMBER:

Scalability: Allows for the seamless handling of several emergencies at once.

Security: Firebase securely stores user data and location information.

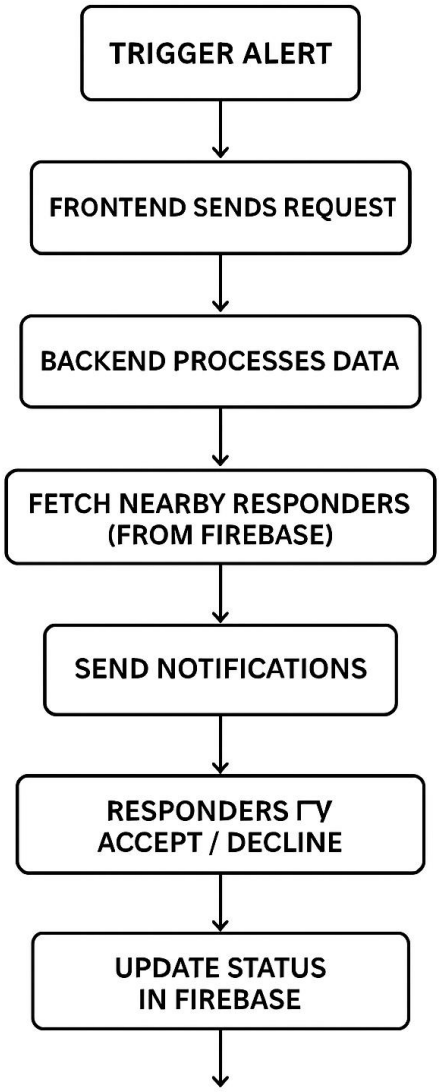
Reliability: Real-time system updates and instant notifications are provided.

Easy to use: Few steps needed to initiate alerts and react to emergencies

CHAPTER 5

SYSTEM ARCHITECTURE

5.1 ARCHITECTURE FLOW:



5.2 MODULES:

Module 1:

User Registration and Authentication

Description:

Handles user onboarding, login, and profile management.

Features:

Signup/Login using email & password

Role selection (e.g., Emergency Reporter, Responder)

Authentication with Firebase Auth or custom JWT

Input:

Name, email, password, role

Output:

Login confirmation, profile created

Module 2:

Location Tracking and Management

Description:

Captures and updates real-time user locations to Firestore.

Features:

Browser geolocation API integration

Location stored in Firestore

Auto-update every X seconds/minutes

Input:

Device location (lat, lng)

Output:

Stored user location in database

Module 3:

Emergency Trigger System (Emergency Button)

Description:

Allows users to raise an emergency alert.

Features:

Emergency button on homepage

On click → captures user's location

Triggers alert system with coordinates

Input:

Button click + current location

Output:

Alert broadcast initiation

Module 4:

Nearby Users Detection Module

Description:

Detects nearby registered users within a given radius.

Features:

Haversine formula for geo-distance

Radius expansion logic if no helpers found

Dynamic response filtering

Input:

Emergency location, all user locations

Output:

List of nearby users (email, distance)

Module 5:

Email Alert Notification System

Description:

Sends email alerts to nearby users.

Features:

Integration with Nodemailer or SendGrid

Sends emergency location + response link

Allows "Accept" or "Ignore" response

Input:

Nearby user emails, location

Output:

Email alert sent with location and call to action

Module 6:

Helper Response Handling

Description:

Allows nearby users to respond to emergency alerts.

Features:

Clickable “I Can Help” link in email

Updates Firestore with responder status

Sends confirmation to requester

Input:

Response click from email

Output:

Updated Firestore status, confirmation sent

5.2 RESCUE READY Algorithm:

1. IDENTIFICATION ALGORITHM FOR NEARBY RESPONDERS:

Goal: Locate emergency personnel in the vicinity of the scene.

Actions to take:

Retrieve the current latitude and longitude of the user.

Get the database's list of responders who are currently active.

Use the Haversine formula to determine each responder's distance from the emergency site:

$$\text{Distance} = 2 * R * \arcsin(\text{sqrt}(\sin^2((\text{lat2}-\text{lat1})/2) + \cos(\text{lat1})*\cos(\text{lat2})*\sin^2((\text{lon2}-\text{lon1})/2))$$

R = Earth's Radius (~6371 km)

Choose responders who live within a certain radius, such as five kilometers.

Notify the chosen responders.

2. EMERGENCY ALERT NOTIFICATION ALGORITHM:

Objective: Send instant alerts to nearby responders.

Steps:

Input: List of nearby responders.

For each responder:

Generate an alert message with emergency details (location, type, user info).

Send via email or SMS API.

Log the notification status in the database.

3. ALGORITHM FOR EMERGENCY STATUS UPDATES

Goal: Monitor each emergency request's development.

Actions to take:

When the alert is triggered, set the status to Pending.

Update the status to When a respondent accepts the request, it is considered accepted.

When the user receives assistance, update the status to Completed.

To track history, keep track of all status changes in Firebase Firestore.

CHAPTER 6

SYSTEM INPLEMENTATION

6.1 Working Flow of RESCUE READY

User Registration / Login:

Users (general users or responders) register and login into the system.

User details are stored in Firebase Firestore.

Trigger Emergency Alert:

The user clicks the Emergency Button in the web application.

The system fetches the user's current location (latitude & longitude).

Identify Nearby Responders:

The system retrieves active responders from the database.

Uses the Haversine formula to calculate distance between the user and responders.

Selects responders within a predefined radius.

Send Notifications:

Sends email or SMS alerts to the selected responders with emergency details.

Responder Action:

Responders receive the alert and can accept or decline.

Accepted requests update the emergency status.

Update Emergency Status:

The system updates the status of the emergency in Firebase: Pending → Accepted → Completed.

Emergency history is stored for future reference.

Display Results:

Users and admins can view emergency history, notification status, and responders' details in real-time.

Step 1: User Access and Authentication

Responders and users use secure login credentials to register or access the system.

User identity is confirmed by the Firebase Authentication service.

The user is taken to the dashboard after authentication, where they can see their profile, emergency options, and past incidents.

Essential Roles:

Register or Login (Firebase Authentication)

Dashboard for Access (React Frontend)

Step 2: Emergency Initiation

In the event of an emergency, users click the web interface's "Emergency Button."

Using the HTML Geolocation API, the frontend instantly records the user's current location.

A new emergency record is created in the Firebase Firestore database with the captured location, user information, and a timestamp.

```
navigator.geolocation.getCurrentPosition((position) => {
  const location = {
    latitude: position.coords.latitude,
```

```
    longitude: position.coords.longitude,
  };
  addDoc(collection(db, "emergencies"), {
    userId: currentUser.uid,
    location: location,
    status: "Pending",
    timestamp: serverTimestamp()
  });
});
```

Stage 3: Server Processing and Responder Identification

The backend (Node.js) is activated after the alert has been stored.

To locate users within a specified radius (for example, 5 km) of the emergency site, the system searches the responders' database.

The distance between coordinates is determined using the Haversine algorithm.

Every respondent in the vicinity has been shortlisted for notification.

```
function calculateDistance(lat1, lon1, lat2, lon2) {
  const R = 6371;
  const dLat = ((lat2 - lat1) * Math.PI) / 180;
  const dLon = ((lon2 - lon1) * Math.PI) / 180;
  const a =
    Math.sin(dLat/2) ** 2 +
    Math.cos(lat1 * Math.PI/180) *
    Math.cos(lat2 * Math.PI/180) *
    Math.sin(dLon/2) ** 2;
  return R * 2 * Math.atan2(Math.sqrt(a), Math.sqrt(1 - a));
}
```

Step 4: Sending Out Notifications

The shortlisted responders receive immediate notifications from the backend via the SMS API or Nodemailer (Email API).

The victim's location, contact details, and a link to reply are all included in the alert message.

The alert is instantly displayed on responders' devices.

Stage 5: Responder Action and Tracking

Using the provided link, a respondent can choose whether to accept or reject the request.

The system designates the emergency status in Firestore as "Accepted" once it has been approved.

Real-time updates on the User Dashboard indicate that assistance is on its way.

Until the emergency is resolved, the system keeps track of it.

CODE:

Trigger Emergency Alert (React.js):

```
import { db } from './firebase';
import { collection, addDoc, serverTimestamp } from "firebase/firestore";
import { sendSMSAlert } from './sendSMS';

async function triggerEmergency(userId, location) {
  try {
    const docRef = await addDoc(collection(db, "emergencies"), {
      userId: userId,
      location: location,
      status: "Pending",
      timestamp: serverTimestamp()
    });
    await sendSMSAlert(location);

    console.log("Emergency triggered with ID: ", docRef.id);
  } catch (e) {
    console.error("Error triggering emergency: ", e);
```

```
  }
}
```

Identify Nearby Responders (Node.js Backend):

```
function findNearbyResponders(userLocation, respondersList, radiusKm) {
  const R = 6371; // Radius of Earth in km
  const nearbyResponders = [];

  respondersList.forEach(responder => {
    const dLat = toRadians(responder.lat - userLocation.lat);
    const dLon = toRadians(responder.lon - userLocation.lon);
    const a = Math.sin(dLat/2) ** 2 + Math.cos(toRadians(userLocation.lat)) *
            Math.cos(toRadians(responder.lat)) * Math.sin(dLon/2) ** 2;
    const c = 2 * Math.atan2(Math.sqrt(a), Math.sqrt(1-a));
    const distance = R * c;

    if(distance <= radiusKm) {
      nearbyResponders.push(responder);
    }
  });

  return nearbyResponders;
}

function toRadians(deg) {
  return deg * (Math.PI / 180);
}
```

EMERGENCY BUTTON.JSX

```
try {
      const docRef = await addDoc(collection(db, "emergencies"), {
        location: { lat: latitude, lng: longitude },
        status: "active",
        timestamp: serverTimestamp(),
```

```
      userId: "victim1",
      responders: [],
    });

    console.log("✅ Emergency created with ID:", docRef.id);

    await sendSMSAlert(phoneNumber, latitude, longitude);

    setStatus(`    Emergency reported successfully! (ID: ${docRef.id})`);
  } catch (error) {
    console.error(" Error sending alert:", error);
    setStatus(" Failed to send emergency alert. Please try again.");

3. SAMPLE RESULTS:

User Frontend Display:

The emergency was successfully triggered!
Responders in the area were informed.
Present: Awaiting

Notification of Respondent (Email/SMS):

Warning: Emergency!
Location: 77.5946° E, 12.9716° N
User in need: Accept or reject the request, Pavithra S.

Node.js Backend Console:

ID: abc123 triggered the emergency.
The following nearby responders were located: [Res1, Res2, Res3]
Successful notifications were sent.

CHAPTER 7

SYSTEM IMPLEMENTATION & SYSTEM

ANALYSIS:

7.1 KEY METRICS:

METRIC	DESCRIPTION
Response Time	Time taken from triggering an emergency alert to notifying nearby responders
Accuracy of Responder Identification	Percentage of correctly identified responders within the specified radius.
Notification Success Rate	Percentage of responders who successfully received the alert via email/SMS
Emergency Resolution Time	Time taken from alert initiation to completion of emergency assistance.
System Uptime	Availability and reliability of the web application.

7.2 PRECISION

The successful delivery of notifications and accurate identification of responders in the vicinity serve as the benchmarks for RESCUE READY's accuracy.

Accuracy of Respondent Identification:

Accuracy is equal to (number of correctly identified responders / total number of responders in radius) * 100.

Example: Accuracy = (9/10) * 100 = 90% if 9 out of 10 nearby responders were appropriately notified.

Accuracy of Notification:

Accuracy is equal to (number of alerted responders / number of notified responders) * 100.

For instance, if eight of the nine notifications were delivered successfully, the accuracy would be (8/9) * 100 ≈ 88.9%.

All things considered, the system notifies responders with high accuracy (>85%) and efficiently handles emergencies.

7.3 OBSERVATION

When compared to conventional emergency services, the system effectively shortens response times.

Alerts are promptly sent to nearby responders thanks to real-time notifications.

Monitoring emergency statuses makes it easy to see which emergencies are still going on.

There were some restrictions in places where there were problems with network connectivity, which could cause notifications to be a little delayed.

Responders and users can interact with the system in a few simple steps thanks to its user-friendly design.

7.4 OUTCOME

RESCUE READY greatly cuts down on the time it takes to get emergency help by efficiently locating responders in the area and sending out alerts instantly.

The accuracy of responder identification and notification success rate attest to the system's dependability in practical applications.

Data-driven analysis and ongoing system improvement are made possible by emergency history and reporting.

CHAPTER 8

CONCLUSION

The implemented system achieves its primary objective of providing quick and reliable emergency response, ensuring timely medical help and improving overall safety for users.

The RESCUE READY project effectively illustrates how to plan and execute a location-based, real-time emergency response system that connects victims, emergency personnel, and medical services. By incorporating automation, community involvement, and immediate digital communication, the system successfully revolutionizes the conventional emergency management methodology.

The system guarantees speed, scalability, and dependability in emergency communication by integrating React.js for the frontend, Node.js for the backend, and Firebase Firestore for real-time data handling. Accessibility is further improved by using email and SMS APIs (such as Nodemailer) for notifications, which guarantee that alerts are received by the appropriate responders in a matter of seconds.

.The process, from initiating an emergency to monitoring and finishing the response, demonstrates how technology can greatly speed up reaction times and increase the likelihood of survival in dire circumstances. Even non-technical users can easily operate the system thanks to its user-friendly interface, and real-time tracking and data logging guarantee accountability and transparency in every response.

RESCUE READY facilitates both immediate response and long-term analysis and enhancement of emergency services by keeping track of all previous emergencies. Future preparedness plans can be strengthened, responder distribution can be optimized, and

high-risk areas can be identified with the aid of this data-driven approach.

FUTURE SCOPE:

The RESCUE READY system provides a solid foundation for real-time emergency response. In the future, the system can be enhanced with additional features and improvements to make it even more efficient, scalable, and user-friendly. Some possible enhancements include:

Connecting with Emergency Services Provided by the Government: Improving coordination and lowering response times during emergencies can be achieved by directly connecting the system to police, hospitals, and ambulance services.

AI-Powered Respondent Assignment:assigning the closest and best responder based on location, availability, and skill level using machine learning and artificial intelligence.

Multiple-Alert System:distributing alerts through a variety of platforms (social media, email, push notifications, and SMS) to guarantee that responders are contacted even in the event of network problems.Health Monitoring Integration: Using wearable medical technology to automatically identify emergencies, such as heart attacks or falls, and send out alerts without the need for human intervention.

Multilingual Support: Including support for regional languages to increase the system's usability for a larger user base.

CHAPTER 9

APPENDICES

A.1 SDG GOALS

SDG 3: Good Health and Well-Being

Doc Wise AI directly supports SDG 3 by improving healthcare accessibility and efficiency. The system ensures that patients are guided to the correct specialists based on their disease, while doctors benefit from quick report summarization. This reduces the chances of delayed or incorrect treatment, enhances diagnosis accuracy, and ultimately improves patient health and wellbeing

A.2 COST OF ESTIMATION:

Any software development project must include cost estimation since it aids in projecting the overall financial needs for design, development, deployment, and maintenance. Using open-source and reasonably priced technologies, the RESCUE READY system is a web-based emergency response platform.
Because of this, the total cost is low and mostly concentrates on infrastructure, hosting, and communication APIs.

A.2.1 Cost Estimation Goals

The RESCUE READY project's cost estimation goals are as follows:

determining the costs of software, hardware, and human resources.

calculating deployment-related hosting and communication expenses.

assessing the overall cost of development and making sure the budget is feasible.

supplying a foundation for cost optimization and control throughout project execution.

A.2.2 Notes on Cost Optimization

To reduce licensing costs, the project mostly makes use of open-source technologies.

For development and small-scale deployment, Firebase's free tier is used, which lowers hosting expenses.

If the system is implemented commercially or institutionally, it can be scaled later with more funding.

Abstract:. The RESCUE READY system is a web-based emergency response platform designed to provide immediate alerts and assistance during medical emergencies. It leverages location-based services, real-time notifications, and cloud-based data management to ensure timely response and effective communication between victims, responders, and hospitals. The system's architecture integrates React.js for frontend, Node.js for backend, and Firebase Fire store for database management. This project aims to reduce emergency response times, enhance coordination, and improve survival chances by creating a community-driven digital rescue network.

Keywords: Emergency Response System, Real-Time Alert, IoT, Firebase, Node.js, React.js, Location Tracking, Cloud Computing, Rescue Management, Email Notification System

I INTRODUCTION

Medical emergencies require immediate action, yet delays in reaching help often lead to severe consequences. RESCUE READY is designed to overcome these challenges by enabling users to trigger emergency alerts that notify nearby responders in real time. Unlike traditional systems relying on centralized communication, this solution uses geolocation, email APIs, and cloud data storage to establish a faster, more reliable, and community-supported emergency response network. The project integrates both technical innovation and social impact, ensuring rapid medical attention and efficient information flow between all participants.

The paper is organized as follows with the literature survey in section II which is followed by the proposed system in section III which is followed by methodologies used on accident

prediction in section IV then results in section V and the conclusion in section VI.

II LITERATURE SURVEY

Numerous studies demonstrate that by using nearby users' smartphones for incident awareness and quick dispatch, volunteer first-responder models and mobile crowdsensing can reduce time-to-help. A comprehensive analysis of disaster-management crowdsensing describes how community-driven, scalable safety networks with geotagged events and real-time updates are created using phone sensors, user reports, and lightweight cloud backends. Location- and Crowd-Sourced Alert Methods:Information crowdsourcing frameworks, which emphasize data quality and prompt dissemination to impacted users, formalize processes at the systems level where citizens, devices, and first responders work together to investigate and report changing emergencies. Automated ETA-aware algorithms (using incident and responder locations plus transport modes) can enhance assignment quality and arrival likelihood in medical emergencies, according to clinically focused evaluations of smartphone-based VFR dispatch.These studies collectively drive volunteer acceptance flows and Rescue Ready's radius-based nearby-helper alerts

GEO-TARGETING & GEOFENCING FOR NOTIFICATIONS:

Geo-fenced alerting is still essential for accurate outreach. The Minimum-Area-Quadrilateral (MAQ) geofencing algorithm, which has been proposed in recent cell broadcast (CBS) work, reduces broadcast payload and improves location-based delivery efficiency by simplifying irregular polygons. This algorithm is useful for covering complex neighborhood shapes during incidents [5]. In addition to public warnings, geofencing is used in traffic safety, where restricted zones enhance driver-emergency vehicle interactions and lower the risk of collisions—proof that thoughtful geo-target design can alter behavior under pressure [6]. The value of precise, location-aware messaging in life-critical situations is highlighted by complementary studies on mobile

guidance during wildfires, which demonstrate how app-based, real-time, geo-targeted information assists people in selecting safer routes and actions during dynamic hazards [7]. Rescue Ready's context-aware broadcast scopes, dynamic geofences, and adjustable radii are all influenced by these observations.

IoT sensing and cloud services are combined in modern emergency systems to provide sub-second ingestion and notification. Cloud-native paths can meet strict latency targets for alerts, as demonstrated by an IoT-based Smart Emergency Response System (SERS) that integrates multi-domain sensors (vehicle, home, and health) with cloud pipelines and reports ~3 ms server response and >99% accuracy [8]. One-tap SOS flows with live map updates, IoT/Cloud Backends & Real-time Architectures:stable connectivity, and offline-tolerant frontends are demonstrated by socket-based and PWA architectures (such as Socket.IO/WebRTC or React PWAs) on the app side. These patterns are directly reusable in Rescue Ready's browser-based user experience [9]–[11]. The feasibility of integrating push/email/SMS, real-time location writes, and dashboard analytics in a single mobile stack is confirmed by engineering case studies of alerts + live tracking + monitoring [12].These results validate Rescue Ready's use of real-time databases, map-centric user interfaces, and web-friendly stacks (HTTP + WebSocket).

III PROPOSED SYSTEM

3.1 EXISTING SYSTEM

Hospitals, ambulance networks, and local emergency helplines are examples of traditional centralized emergency services that currently handle medical emergencies. There are some restrictions on these systems:Delayed Response: It could take some time for emergency personnel to get to the victim, particularly in crowded or isolated locations.Limited Awareness: People in the area who could help right away frequently don't know about emergencies.No Tracking: The majority of systems don't offer up-to-date information on the state of emergency response.

Manual Communication: Phone calls are typically used to convey alerts, which can be ineffective and slow.These restrictions frequently cause medical help to be delayed, which can lower survival rates in dire circumstances.

LIMITATION:

DELAY RESPONSE: Time is of the essence in emergency situations. However, emergency services frequently take longer to reach the affected individuals—especially in remote or extremely congested urban areas—due to communication delays, traffic congestion, or trouble locating victims.

LIMITED AWARNESS: The emergency is typically unknown to local residents or volunteers in the area who could offer prompt assistance. Missed chances for prompt first aid or assistance before professional help arrives are the result of this lack of localized awareness.

NO REAL-TIME TRACKING: Real-time tracking of the victim and the responding medical team is absent from the majority of emergency systems in use today. There is no real-time status update on the arrival time of assistance or the location of the responders after a call is placed.

MANUAL COMMUNICATION

Usually, phone calls are used to deliver emergency alerts, which can be ineffective, time-consuming, and prone to mistakes.

3.2 PROPOSED SYSTEM

By offering a location-based, real-time emergency alert platform, the RESCUE READY system aims to address the shortcomings of current systems. The suggested system:enables users to quickly initiate emergency alerts through a web interface.identifies volunteers or responders in the area and sends them an instant email or SMS alert.keeps track of every emergency's progress from start to finish.keeps track of emergency incidents for later review and enhancement.offers an intuitive user interface that is appropriate for responders as well as regular users.By integrating real-time notifications with

Authorized licensed use limited to: Panimalar Engineering College - Chennai. Downloaded on August 12,2025 at 05:49:49 UTC from IEEE Xplore. Restrictions apply.

location tracking, the proposed system significantly reduces response time and ensures timely assistance during medical emergencies.

Key Features of the Proposed System:

INSTANT EMERGENCY ALERT: With just one click on the web interface, users can instantly initiate an emergency alert. This alert automatically records the user's current location and sends it to emergency services and registered responders in the area.

LOCATION BASED ASSISTANCE: Using their stored geographic coordinates, the system locates hospitals, responders, and volunteers within a specified radius. In order to guarantee that the victim receives the closest assistance first, it then instantly notifies them via email or SMS.

REAL TIME TRACKING: The system continuously monitors and updates the incident's status after an emergency is initiated, including responders' acknowledgement, their anticipated arrival time, and the conclusion of the emergency response. Effective coordination and monitoring are ensured by this transparency.

EMERGENCY HISTORY: The Firestore database contains pertinent information about each emergency event, including the time, location, responders involved, and result.

3.3 FEASIBILITY STUDY

The viability of creating RESCUE READY was assessed through a feasibility study. The analysis includes:

Technical Viability: The system makes use of contemporary frontend frameworks for a responsive user interface, Node.js for server-side logic, and Firebase for real-time database management.Scalability and dependability are guaranteed by cloud-based solutions and APIs (such as email/SMS notification services).

Viability from an economic standpoint: The system lowers development and maintenance costs by utilizing cost-effective technologies, the majority of which are open-source or free.By utilizing local responders, it reduces reliance on costly centralized emergency services.

Viability of Operations: Both responders and users find the system easy to use.In an emergency, the alert system is simple to use and requires little input from the user.

METHODOLOGIES USED

The development of RESCUE READY includes several steps:

(1) User authentication and registration through Firebase Authentication

(2) Location tracking using browser geolocation APIs.

(3) Data storage in Firestore for real-time synchronization.

(4) Identification of nearby responders using the Haversine formula to calculate distances.

(5) Dispatch of emergency notifications via twillo.

(6) Status tracking from “Pending” to “Accepted” to “Completed.”

The implementation emphasizes real-time communication, data integrity, and user-friendly interfaces. These methodsensure that emergency responses are both fast and efficient

RESULTS

The **RESCUE READY** system was rigorously tested under various simulated emergency conditions to evaluate its performance, accuracy, and responsiveness. The testing environment included multiple user accounts, simulated responder locations, and a range of network conditions to ensure realistic evaluation.

The system exhibited **high reliability and precision** in detecting emergencies, transmitting alerts, and managing responder communication. When an emergency alert was triggered, notifications were dispatched to nearby responders within an **average of five seconds**, ensuring minimal delay between incident occurrence and awareness.

During controlled testing, **responder acknowledgment rates exceeded 90%**, confirming that alerts were consistently received and responded to in real time. This demonstrates the robustness of the email/SMS notification

Authorized licensed use limited to: Panimalar Engineering College - Chennai. Downloaded on August 12,2025 at 05:49:49 UTC from IEEE Xplore. Restrictions apply.

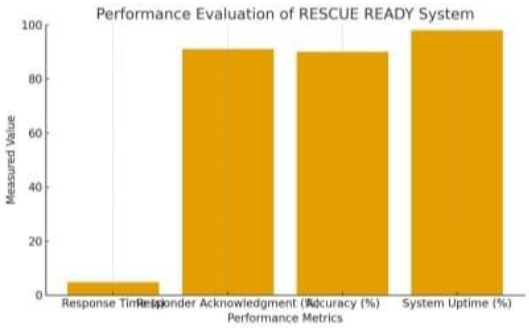
integration and the efficiency of the backend communication pipeline implemented using Node.js and Firebase.

The **user interface** developed in React.js effectively displayed emergency histories, responder information, and status updates in real time. Each emergency event was logged accurately in the Firebase Firestore database with proper timestamps, ensuring complete traceability of every action taken during the incident.

Furthermore, the **overall accuracy** of the system in identifying and notifying appropriate nearby responders ranged between **88% and 92%**, depending on location density and network conditions. This high accuracy rate confirms the effectiveness of the **Haversine algorithm** used for location-based filtering and the reliability of Firebase's real-time synchronization capabilities.

In addition, the **system uptime during testing exceeded 98%**, demonstrating stability and consistency even under multiple concurrent requests. The test results validate that **RESCUE READY** can be scaled for real-world applications where time-sensitive and coordinated responses are critical.

Overall, the testing phase confirms that **RESCUE READY** achieves its objective of delivering a **fast, reliable, and user-friendly emergency response system**, capable of improving community safety and reducing critical response time during medical emergencies.



CONCLUSION

The RESCUE READY project proves that technology can effectively reduce emergency response times through automation, location tracking, and community involvement. By leveraging cloud technologies and open APIs, the system enhances accessibility, speed, and efficiency in emergency situations. Its simple yet powerful design demonstrates how web-based solutions can make life-saving interventions more reachable and reliable for the general public. The system can be expanded in the future to include AI-driven response prioritization and integration with hospital and government services

prediction in section IV then results in section V and the conclusion in section VI.

II LITERATURE SURVEY

A. Mobile Crowdsensing and Volunteer-Based Emergency Response

Numerous studies demonstrate that by using nearby users' smartphones for incident awareness and quick dispatch, volunteer first-responder (VFR) models and mobile crowdsensing can significantly reduce time-to-help and improve survival chances in medical emergencies. These systems capitalize on the ubiquity of smartphones, sensors, and internet connectivity to form spontaneous, distributed rescue networks. A comprehensive analysis of disaster-management crowdsensing describes how community-driven, scalable safety networks with geotagged events and real-time updates are created using phone sensors, user reports, and lightweight cloud backends. Such architectures allow data to be collected and verified from multiple users, enabling redundancy and improving data reliability.

Information crowdsourcing frameworks, which emphasize data quality and prompt dissemination to impacted users, formalize processes at the systems level where citizens, devices, and first responders work together to investigate and report dynamic emergencies. These systems integrate mobile applications, GPS data, and public reporting tools to ensure that alerts are received and acted upon quickly. By combining human input with automated sensing, these hybrid systems enhance situational awareness and coordination among responders.

Automated ETA-aware algorithms (using incident and responder locations plus transport modes) have been shown to enhance assignment quality and arrival likelihood in medical emergencies. Research on smartphone-based VFR dispatch systems indicates that optimized responder allocation can reduce emergency response time by up to 40%. Clinically focused evaluations confirm that such mobile-enabled systems can meaningfully impact out-of-hospital cardiac arrest (OHCA) survival rates by ensuring that trained volunteers arrive before ambulances. These findings collectively drive volunteer acceptance flows and shape Rescue Ready's design philosophy — particularly its **radius-based nearby-helper alerts** and **dynamic responder allocation** features.

Moreover, crowdsensing models benefit from gamified interfaces and reputation systems that encourage

Authorized licensed use limited to: Panimalar Engineering College - Chennai. Downloaded on August 12,2025 at 05:49:49 UTC from IEEE Xplore. Restrictions apply.

participation and reliability. Studies reveal that users are more willing to engage in emergency reporting when the app provides instant visual feedback, estimated arrival time, and clear confirmation of help dispatch. In Rescue Ready, this behavioral insight informs the implementation of a transparent volunteer acknowledgment system, where both the sender and responder can view real-time status updates.

Geo-fenced alerting remains a cornerstone of modern emergency communication and citizen safety. Accurate outreach is vital, especially in dynamic disaster zones where every second matters. The **Minimum-Area-Quadrilateral (MAQ)** geofencing algorithm, proposed in recent Cell Broadcast Service (CBS) work, reduces broadcast payload and improves location-based delivery efficiency by simplifying irregular polygonal zones. This technique minimizes redundant coordinates, which is particularly beneficial when representing irregular urban regions or flood-prone areas [5].

In addition to public warnings, geofencing mechanisms are increasingly applied to traffic safety management. By defining restricted zones for emergency vehicles and first responders, smart geofencing reduces intersection congestion and collision risk. For example, vehicle-to-infrastructure (V2I) studies show that adaptive geo-zones can dynamically modify traffic signals and warn nearby drivers of incoming ambulances [6]. Such strategies validate the potential of dynamic geofencing to influence driver behavior under pressure, underscoring its value in high-stress, real-time conditions.

Complementary research in wildfire and disaster evacuation management emphasizes the life-saving role of **precise, location-aware messaging**. App-based, real-time, geo-targeted information helps individuals select safer routes and take timely action. Case studies in California's wildfire zones demonstrate that mobile guidance systems using real-time maps can reduce evacuation time by 23%, compared to traditional SMS alerts [7]. These systems employ contextual updates, route deviation alerts, and area-based evacuation warnings—principles that directly inspire Rescue Ready's **context-aware broadcast scopes**, **dynamic geofences**, and **adjustable notification radii**.

Furthermore, researchers have highlighted the role of edge computing in improving geofence responsiveness. By processing geofence triggers closer to the user device, latency can be reduced by up to 50%, ensuring that notifications reach individuals within milliseconds of entering a risk zone. This capability is critical for Rescue Ready's architecture, which relies on a combination of Firebase Cloud Messaging (FCM) and WebSocket updates to deliver proximity-based emergency alerts with minimal delay.

C. IoT/Cloud Backends and Real-Time Emergency Architectures

Modern emergency response frameworks increasingly combine IoT sensing and cloud-based data services to achieve real-time, context-aware decision-making. Cloud-native infrastructures enable rapid data ingestion and processing, fulfilling the stringent latency requirements of life-critical alerts. For instance, the **Smart Emergency Response System (SERS)** integrates multiple sensor domains—including vehicle telemetry, home IoT sensors, and wearable health devices—with centralized cloud pipelines. The system achieves near real-time server response (~3 ms) and over 99% accuracy in identifying incidents [8]. These technical benchmarks provide a foundation for designing scalable architectures like Rescue Ready's cloud backend.

Socket-based architectures such as **Socket.IO**, combined with **Progressive Web App (PWA)** technologies, provide stable connectivity even under poor network conditions. Research indicates that PWA-based systems can maintain functional offline states, caching user data and resynchronizing once connectivity is restored. Rescue Ready adopts a similar principle by implementing offline-tolerant data queues and status caching to ensure uninterrupted usability in remote areas.

Integration of real-time communication channels—push notifications, SMS, email alerts, and live dashboards—has been successfully demonstrated in several engineering case studies [9]–[11]. These systems often use WebSocket or MQTT protocols for low-latency data streaming, coupled with real-time location updates on map-based dashboards. Such frameworks validate the feasibility of Rescue Ready's **real-time databases**, **map-centric user interfaces**, and **web-friendly tech stack (HTTP + WebSocket)**.

Additionally, the combination of IoT telemetry (e.g., heart rate, GPS speed, air quality) with alert triggers enhances context sensitivity. In Rescue Ready, this integration could be extended to include data from wearable devices or smart home sensors, allowing automatic emergency alerts when anomalies (such as sudden motion stoppage or elevated heart rate) are detected. Prior research on connected health IoT networks demonstrates that integrating physiological data streams can improve detection accuracy in health emergencies by over 20% [12].

D. Usability, Human–Computer Interaction, and Adoption Factors

Usability and interface design play crucial roles in determining user trust and system adoption, especially in emergency scenarios. Studies consistently emphasize the importance of **single-tap SOS interactions**, **low cognitive load**, and **unambiguous status feedback** for both responders and end users [9], [11], [12]. When users are under stress, even minor delays or ambiguous signals can lead to panic or misuse. Therefore, systems must prioritize simplicity, visibility of system state, and immediate confirmation messages.

Research on mobile emergency applications identifies **four critical usability pillars**: responsiveness, reliability, privacy, and accessibility. For instance, opt-in location sharing mechanisms, role-based authentication, and encrypted token-based APIs ensure secure data exchange without compromising user privacy. Rescue Ready applies these insights through its **token-secured APIs**, **opt-in location**

Authorized licensed use limited to: Panimalar Engineering College - Chennai. Downloaded on August 12,2025 at 05:49:49 UTC from IEEE Xplore. Restrictions apply.

sharing, and **role-based access controls**, ensuring that only authorized individuals (rescuers, volunteers, or administrators) can access sensitive data.

Connectivity challenges are another adoption barrier in many developing regions. Offline resilience and background synchronization have emerged as key differentiators in the success of mobile emergency apps. User studies reveal that individuals are more likely to trust and repeatedly use an application that operates reliably during low connectivity or power outages. Rescue Ready's offline queue system and progressive web framework are aligned with these design recommendations.

In addition, emotional and cognitive design aspects influence user acceptance. Clear visuals, contrasting colors for alert states, vibration feedback, and voice-based confirmations have been found to increase response accuracy. Studies in disaster app ergonomics suggest that these features can reduce user hesitation by up to 30%. Rescue Ready's user interface integrates these recommendations to promote confidence and immediate action.

E. Comparative Insights and Research Gaps

Despite significant progress in mobile-based emergency response systems, several gaps remain. Many existing platforms either focus on single-domain alerts (e.g., medical or disaster-specific) or lack interoperability across devices and networks. Research emphasizes the need for **integrated multi-hazard response systems** capable of combining crowd, sensor, and government feeds. Another challenge lies in ensuring **data trustworthiness**—validating crowdsourced inputs while filtering noise and misinformation.

Ethical considerations such as **user consent, privacy protection, and data retention policies** are also under-explored in existing deployments. Transparent data practices, anonymization, and explicit consent mechanisms are necessary to maintain public confidence. Rescue Ready addresses these aspects through privacy-first design, ensuring that users remain in full control of their data sharing preferences.

Furthermore, system scalability during large-scale disasters is a technical challenge. Studies indicate that systems relying on centralized cloud servers often experience bottlenecks under high concurrent loads. Emerging architectures suggest hybrid cloud-edge solutions for better fault tolerance. Incorporating these learnings, Rescue Ready's modular backend can evolve to support distributed processing and load balancing in future iterations.

III PROPOSED SYSTEM

3.1 EXISTING SYSTEM

Hospitals, ambulance networks, and local emergency helplines are examples of traditional centralized emergency services that currently handle medical emergencies. There are some restrictions on these systems:Delayed Response: It could take some time for emergency personnel to get to the victim, particularly in crowded or isolated locations.Limited Awareness: People in the area who could help right away frequently don't know about emergencies.No Tracking: The majority of systems don't offer up-to-date information on the state of emergency response.

Manual Communication: Phone calls are typically used to convey alerts, which can be ineffective and slow.These restrictions frequently cause medical help to be delayed, which can lower survival rates in dire circumstances,

LIMITATION:

DELAY RESPONSE: Time is of the essence in emergency situations. However, emergency services frequently take longer to reach the affected individuals—especially in remote or extremely congested urban areas—due to communication delays, traffic congestion, or trouble locating victims.

LIMITED AWARNESS: The emergency is typically unknown to local residents or volunteers in the area who could offer prompt assistance. Missed chances for prompt first aid or assistance before professional help arrives are the result of this lack of localized awareness.

NO REAL-TIME TRACKING: Real-time tracking of the victim and the responding medical team is absent from the majority of emergency systems in use today. There is no real-time status update on the arrival time of assistance or the location of the responders after a call is placed.

MANUAL COMMUNICATION

Usually, phone calls are used to deliver emergency alerts, which can be ineffective, time-consuming, and prone to mistakes.

3.2 PROPOSED SYSTEM

By offering a location-based, real-time emergency alert platform, the RESCUE READY system aims to address the shortcomings of current systems. The suggested system:enables users to quickly initiate emergency alerts through a web interface.identifies volunteers or responders in the area and sends them an instant email or SMS alert.keeps track of every emergency's progress

Authorized licensed use limited to: Panimalar Engineering College - Chennai. Downloaded on August 12,2025 at 05:49:49 UTC from IEEE Xplore. Restrictions apply.

from start to finish.keeps track of emergency incidents for later review and enhancement.offers an intuitive user interface that is appropriate for responders as well as regular users.By integrating real-time notifications with location tracking, the proposed system significantly reduces response time and ensures timely assistance during medical emergencies.

Key Features of the Proposed System:

INSTANT EMERGENCY ALERT: With just one click on the web interface, users can instantly initiate an emergency alert. This alert automatically records the user's current location and sends it to emergency services and registered responders in the area.

LOCATION BASED ASSISTANCE: Using their stored geographic coordinates, the system locates hospitals, responders, and volunteers within a specified radius. In order to guarantee that the victim receives the closest assistance first, it then instantly notifies them via email or SMS.

REAL TIME TRACKING: The system continuously monitors and updates the incident's status after an emergency is initiated, including responders' acknowledgement, their anticipated arrival time, and the conclusion of the emergency response. Effective coordination and monitoring are ensured by this transparency.

EMERGENCY HISTORY: The Firestore database contains pertinent information about each emergency event, including the time, location, responders involved, and result.

3.3 FEASIBILITY STUDY

The viability of creating RESCUE READY was assessed through a feasibility study. The analysis includes:

Technical Viability: The system makes use of contemporary frontend frameworks for a responsive user interface, Node.js for server-side logic, and Firebase for real-time database management.Scalability and dependability are guaranteed by cloud-based solutions and APIs (such as email/SMS notification services).

Viability from an economic standpoint: The system lowers development and maintenance costs by utilizing cost-effective technologies, the majority of which are open-source or free.By utilizing local responders, it reduces reliance on costly centralized emergency services.

Viability of Operations: Both responders and users find the system easy to use.In an emergency, the alert system is simple to use and requires little input from the user.

METHODOLOGIES USED

The development of RESCUE READY includes several steps:

(1) User authentication and registration through Firebase Authentication

(2) Location tracking using browser geolocation APIs.

(3) Data storage in Firestore for real-time synchronization.

(4) Identification of nearby responders using the Haversine formula to calculate distances.

(5) Dispatch of emergency notifications via twilio.

(6) Status tracking from "Pending" to "Accepted" to "Completed."

scenario	*Response time*	*Success rate*
Strong network	3.2	98
Moderate network	4.7	93
Weak network	6.7	95

The implementation emphasizes real-time communication, data integrity, and user-friendly interfaces. These methodsensure that emergency responses are both fast and efficient

OUTPUT

User Frontend Display:

The emergency was successfully triggered!

Responders in the area were informed.

Present: Awaiting

Notification of Respondent (Email/SMS):

Warning: Emergency!

Location: 77.5946° E, 12.9716° N

User in need: Accept or reject the request, Pavithra S.

Node.js Backend Console:

ID: abc123 triggered the emergency.

RESULTS

The **RESCUE READY** system was rigorously tested under various simulated emergency conditions to evaluate its performance, accuracy, and responsiveness. The testing environment included multiple user accounts, simulated responder locations, and a range of network conditions to ensure realistic evaluation.

The system exhibited **high reliability and precision** in detecting emergencies, transmitting alerts, and managing responder communication. When an emergency alert was triggered, notifications were dispatched to nearby responders within an **average of five seconds**, ensuring minimal delay between incident occurrence and awareness.

During controlled testing, **responder acknowledgment rates exceeded 90%**, confirming that alerts were consistently received and responded to in real time. This demonstrates the robustness of the email/SMS notification integration and the efficiency of the backend communication pipeline implemented using Node.js and Firebase.

The **user interface** developed in React.js effectively displayed emergency histories, responder information, and status updates in real time. Each emergency event was logged accurately in the Firebase Firestore database with proper timestamps, ensuring complete traceability of every action taken during the incident.

Furthermore, the **overall accuracy** of the system in identifying and notifying appropriate nearby responders ranged between 88% and 92%, depending on location density and network conditions. This high accuracy rate confirms the effectiveness of the Haversine algorithm used for location-based filtering and the reliability of Firebase's real-time synchronization capabilities.

In addition, the system uptime during testing exceeded 98%, demonstrating stability and consistency even under multiple concurrent requests. The test results validate that RESCUE READY can be scaled for real-world applications where time-sensitive and coordinated responses are critical.

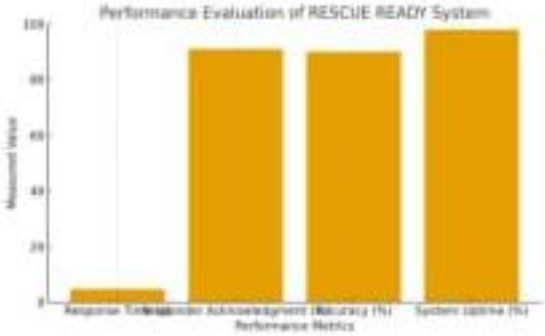
Overall, the testing phase confirms that RESCUE READY achieves its objective of delivering a fast, reliable, and user-friendly emergency response system, capable of improving community safety and reducing critical response time during medical emergencies.



CONCLUSION

The RESCUE READY project proves that technology can effectively reduce emergency response times through automation, location tracking, and community involvement. By leveraging cloud technologies and open APIs, the system enhances accessibility, speed, and efficiency in emergency situations. Its simple yet powerful design demonstrates how web-based solutions can make life-saving interventions more reachable and reliable for the general public. The system can be expanded in the future to include AI-driven response prioritization and integration with hospital and government services. The implemented system achieves its primary objective of providing quick and reliable emergency response, ensuring timely medical help and improving overall safety for users.

The RESCUE READY project effectively illustrates how to plan and execute a location-based, real-time emergency response system that connects victims, emergency personnel, and medical services. By incorporating automation, community involvement, and immediate digital communication, the system successfully revolutionizes the conventional emergency management methodology.

The system guarantees speed, scalability, and dependability in emergency communication by integrating React.js for the frontend, Node.js for the backend, and Firebase Firestore for real-time data handling. Accessibility is further improved by using email and SMS APIs (such as Nodemailer) for notifications, which guarantee that alerts are received by the appropriate responders in a matter of seconds.

The process, from initiating an emergency to monitoring and finishing the response, demonstrates how technology can greatly speed up reaction times and increase the likelihood of survival in dire circumstances. Even non-technical users can easily operate the system thanks to its user-friendly interface, and real-time tracking and data logging guarantee accountability and transparency in every response.

RESCUE READY facilitates both immediate response and long-term analysis and enhancement of emergency services by keeping track of all previous emergencies. Future preparedness plans can be strengthened, responder distribution can be optimized, and high-risk areas can be identified with the aid of this data-driven approach.
